

Transient Threats - What are Transients?

Voltage Transients are defined as short duration surges of electrical energy and are the result of the sudden release of energy previously stored or induced by other means, such as heavy inductive loads or lightning. In electrical or electronic circuits, this energy can be released in a predictable manner via controlled switching actions, or randomly induced into a circuit from external sources.

Repeatable transients are frequently caused by the operation of motors, generators, or the switching of reactive circuit components. Random transients, on the other hand, are often caused by Lightning and Electrostatic Discharge (ESD). Lightning and ESD generally occur unpredictably, and may require elaborate monitoring to be accurately measured, especially if induced at the circuit board level. Numerous electronics standards groups have analyzed transient voltage occurrences using accepted monitoring or testing methods. The key characteristics of several transients are shown in the table below.

	VOLTAGE	CURRENT	RISE-TIME	DURATION
Lightning	25kV	20kA	10 μ s	1ms
Switching	600V	500A	50 μ s	500ms
EMP	1kV	10A	20ns	1ms
ESD	15kV	30A	<1ns	100ns

Table 1: Examples of transient sources and magnitude

Characteristics of Transient Voltage Spikes

Transient voltage spikes generally exhibit a “double exponential” wave, as shown below for lightning and ESD.

Figure 1: Lightning Transient Waveform

Figure 2: ESD Test Waveform

The exponential rise time of lightning is in the range 1.2 μ sec to 10 μ sec (essentially 10% to 90%) and the duration is in the range of 50 μ sec to 1000 μ sec (50% of peak values). ESD on the other hand, is a much shorter duration event. The rise time has been characterized at less than 1.0ns. The overall duration is approximately 100ns.

Why are Transients of Increasing Concern?

Component miniaturization has resulted in increased sensitivity to electrical stresses. Microprocessors for example, have structures and conductive paths which are unable to handle high currents from ESD transients. Such components operate at very low voltages, so voltage disturbances must be controlled to prevent device interruption and latent or catastrophic failures.

Sensitive microprocessors are prevalent today in a wide range of devices. Everything from home appliances, such as dishwashers, to industrial controls and even toys use microprocessors to improve functionality and efficiency.

Most vehicles now also employ multiple electronic systems to control the engine, climate, braking and, in some cases, steering, traction and safety systems.

Many of the sub- or supporting components (such as electric motors or accessories) within appliances and automobiles present transient threats to the entire system.

Careful circuit design should not only factor environmental scenarios but also the potential effects of these related components. Table 2 below shows the vulnerability of various component technologies.

Device Type	Vulnerability (volts)
VMOS	30-1800
MOSFET	100-200
GaAsFET	100-300
EPROM	100
JFET	140-7000
CMOS	250-3000
Schottky Diodes	300-2500
Bipolar Transistors	380-7000
SCR	680-1000

TVS Diode Transient Voltage Scenarios

Electrostatic Discharge (ESD)

Electrostatic discharge is characterized by very fast rise times and very high peak voltages and currents. This energy is the result of an imbalance of positive and negative charges between objects.

ESD that is generated by everyday activities can far surpass the vulnerability threshold of standard semiconductor technologies. Following are a few examples:

- **Walking across a carpet:**
35kV @ RH = 20%; 1.5kV @ RH = 65%
- **Walking across a vinyl floor:**
12kV @ RH = 20%; 250V @ RH = 65%
- **Worker at a bench:**
6kV @ RH = 20%; 100V @ RH = 65%
- **Vinyl envelopes:**
7kV @ RH = 20%; 600V @ RH = 65%
- **Poly bag picked up from desk:**
20kV @ RH = 20%; 1.2kV @ RH = 65%

Lightning Induced Transients

Even though a direct strike is clearly destructive, transients induced by lightning are not the result of a direct strike.

When a lightning strike occurs, the event creates a magnetic field which can induce transients of large magnitude in nearby electrical cables.

A cloud-to-cloud strike will effect not only overhead cables, but also buried cables. Even a strike 1 mile distant (1.6km) can generate 70 volts in electrical cables.

In a cloud-to-ground strike (as shown at right) the transient-generating effect is far greater.

This diagram shows a typical current waveform for induced lightning disturbances.

Inductive Load Switching

The switching of inductive loads generates high energy transients which increase in magnitude with increasingly heavy loads. When the inductive load is switched off, the collapsing magnetic field is converted into electrical energy which takes the form of a double exponential transient. Depending on the source, these transients can be as large as hundreds of volts and hundreds of Amps, with duration times of 400 milliseconds.

Typical sources of inductive transients include:

- **Generator** • **Motor**
- **Relay** • **Transformer**

These examples are common in electrical and electronic systems. Because the sizes of the loads vary according to the application, the wave shape, duration, peak current and peak voltage are all variables which exist in real world transients. Once these variables can be approximated, a suitable suppressor technology can be selected.

The diagram at right shows a transient which is the result of stored energy within the alternator of an automobile charging system.

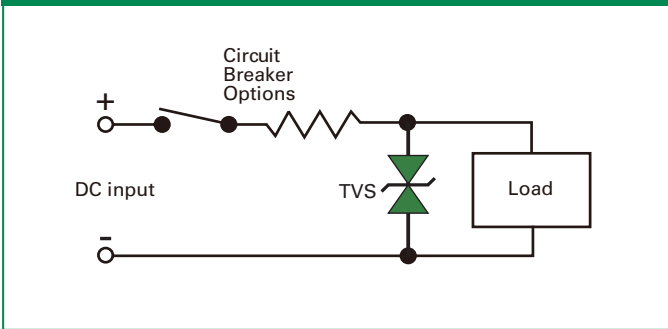

A similar transient can also be caused by other DC motors in a vehicle.

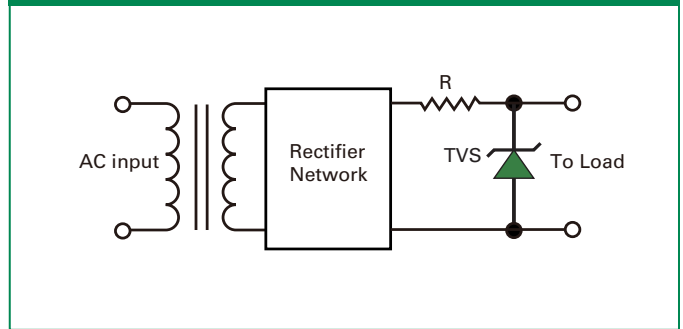

For example, DC motors power amenities such as power locks, seats and windows. These various applications of a DC motor can produce transients that are just as harmful to the sensitive electronic components as transients created in the external environment.

TVS Diode Device Typical Applications

DC Supply Protection

DC Load Protection

AC Supply Protection

Electro-Magnetic Interference Limiting

Operational Amplifier Protection

Combined MOV Varistor and TVS Diode Protection Scenarios

MOV + TVS Combination:

MOV Varistor
 High Energy
 Withstand

TVS Diode
 Low Clamping
 Voltage

MOV + Choke + TVS Combination:

MOV Varistor
 V33ZA70PX
 Special low voltage
 20mm diameter MOV
 3KA@8/20µs (1 time)

TVS Diode
 SMBJ28A/SMBJ30A
 SMCJ28A/SMCJ30A

Telecom DC/DC Protection

Circuit Protection of 24VDC with High Surge Capatbility

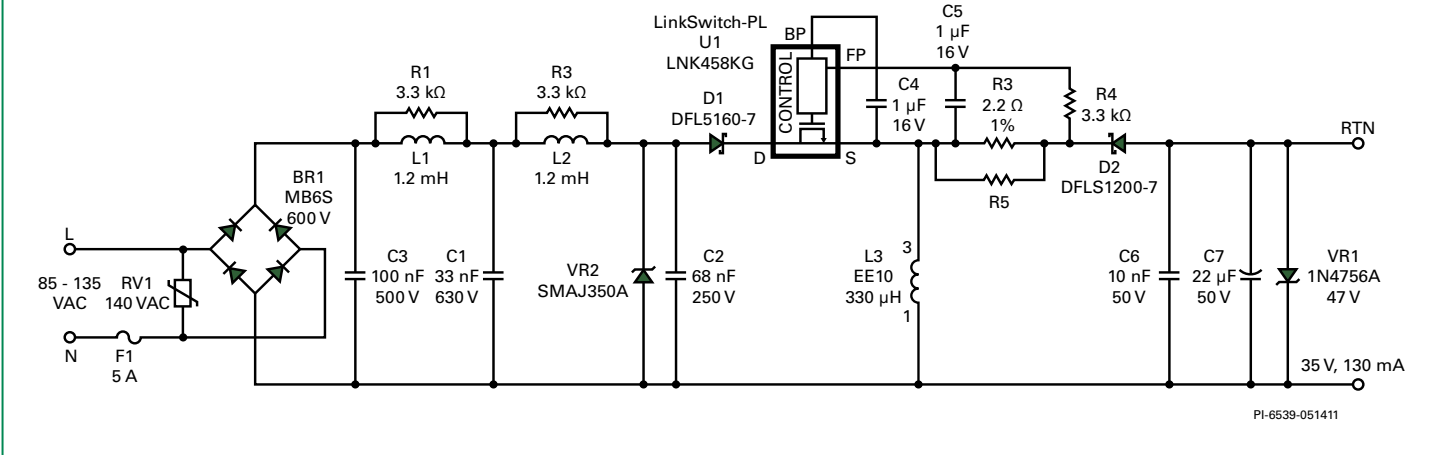

Pulse Width Modulated (PWM) Driver Protection

Power Over Ethernet (PoE) Protection

LED Driver Protection

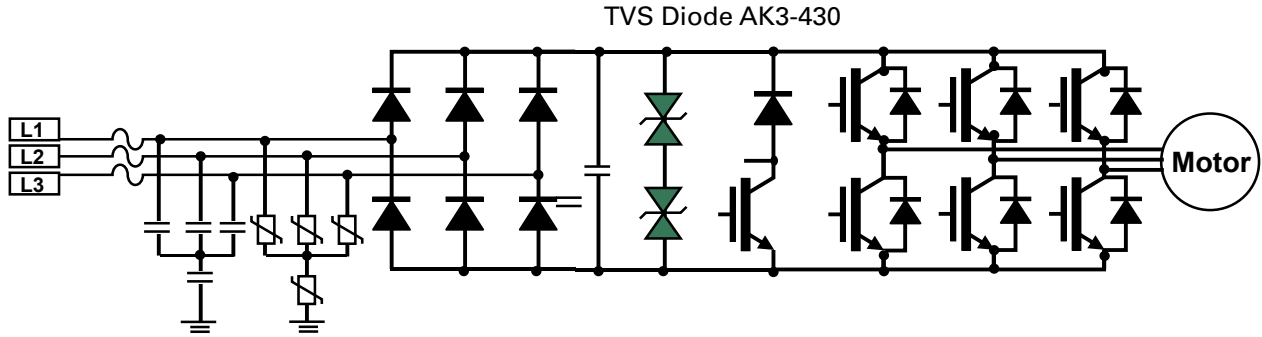

RS485 Interface Protection

RS232 Interface Protection with High Surge Requirement

Inverter / VFD protection in IGBT Module Protection

IGBT Gate Protection
